June 2008

## **ABSTRACT**

This paper explores the determinants of the choice of UK universities by overseas undergraduate applicants. We use data on overseas applicants in Business Studies and Engineering from 2002 to 2007, to 97 UK universities. Estimating using a Hausman-Taylor model to control for the possible correlation between our explanatory variables and unobservable university level effects, we find that the fees charged do not influence the application decision. However, the quality of education provided is positively and significantly related to the number of applications. Proximity to London, the existing popularity of a university among foreign students and among home applicants, are also highly significant predictors of university applications.

JEL Classification: I21, D12

Keywords: UK universities; demand estimation; overseas students.

## I. INTRODUCTION

The higher education sector continues to be an important contributor to the UK economy. In the 2004/5 academic year there were 2.48 million students in higher education in the UK, the sector enjoyed a total income of £18 billion and employed 346,000 people. Overseas students (students from outside of the EU) are an important part of the higher education sector. Again in the 2004/5 academic year, there were approximately 218,000 overseas students, having an estimated direct monetary impact on the UK economy of £2.87 billion (all figures from Vickers and Bekhradnia (2007)). This impact, comprising university fees and living expenditures, may also give rise to substantial multiplier effects, as estimated by Greenaway and Tuck (1995).<sup>1</sup> This impact is in addition to the fact that many overseas graduates find employment in the UK after graduation, thus adding to the pool of highly skilled labour and providing benefits for the UK economy. Overseas students can also be expected to offer a number of non-monetary benefits to universities in terms of diversity of student cohorts and previous experiences, alumni networks etc.

Since the education of overseas students may impose some additional costs on universities, in 1980 the UK Government implemented new rules allowing universities to charge both undergraduate and postgraduate students from outside of the EU (referred to as overseas students) tuition fees reflecting the full cost of provision. This increase in fees had the immediate effect of reducing the number of overseas students choosing to study in the UK (see for example Williams (1987), Moore (1989)). As a result, universities were forced to consider the most effective strategies for regaining overseas student numbers (Woodhall (1989)). Attracting overseas students remains important today, for financial reasons as well as for the diversity of experience that they bring to undergraduate and postgraduate programmes.

Universities have had to consider much more seriously the information that is made readily available to help inform potential student choices. Simultaneously a number of changes have taken place in the higher education sector which have also resulted in an increase in the number of readily available potential quality indicators. For example, successive Research

---

<sup>1</sup> Overseas students may also impose costs on an economy, for example due to costs of health care provision and increasing pressures on the housing market. However, Vickers and Bekhradnia (2007) argue that due to the individual characteristics of university students (especially their age and lack of dependents), they are likely to impose few fiscal costs, and these are outweighed by the multiplier effects on the economy.

Assessment Exercises (RAEs) have provided information on research activities in academic departments, while the Quality Assurance Agency assessed and published information on the quality of teaching. Meanwhile, a number of University Guides, including the Times Guide, the Guardian Guide and the Virgin Guide, collate information on a wide range of factors that might influence student university choice, including RAE and teaching quality scores, but also investment in library, IT and facilities investment, cost and types of accommodation, and other factors. See HEFCE (2008) for a report evaluating five league tables, including The Sunday Times, The Times and The Guardian university guides. These guides provide students with a quick and easy way to compare institutions, and are especially useful to overseas students who do not have the opportunity to visit prospective universities before making their applications. However, the HEFCE (2008) report also identifies shortcomings of the guides and associated league tables, such as their focus on full-time undergraduate provision, and the impact of reputational factors rather than true quality indicators on institutions' standings.

This paper investigates the factors determining overseas students' decisions to apply for an undergraduate degree at a UK university. Understanding these determinants may enable both universities and policymakers to make better decisions in expanding the overseas market for UK higher education. Implicit throughout the analysis is the assumption that when overseas students select a university, this decision is made following two earlier decisions, namely what subject to study, and the country (UK) in which to study. Rather than rely on survey methods to deduce preferences for an overseas tertiary education, or a case study methodology as applied by Chapman and Pyvis (2006), we use UCAS (Universities and Colleges Admissions Service) data on overseas student applications and admissions. We are unaware of other analyses using this or comparable non-UK datasets to model the factors influencing the decision of overseas students to apply to particular universities for undergraduate degrees. The richness of data available on possible factors influencing UK university choice also allows us to use regression methods to estimate the impact of potential explanatory variables.

The literature examining the factors influencing the decisions relating to university study remains limited. Psacharopoulos and Soumelis (1979) and Menon (1998) examine quantitatively the factors influencing school pupils' decisions to attend university (typically in their home nations) of Greece and Cyprus, respectively. However, the analyses do not

relate to specific degree subjects, so attention focuses on individual and family characteristics influencing the decision to attend university, rather than university attributes. Oosterbeek *et al.* (1992) instead use survey data from the Netherlands to identify the factors that influence Economics students' university choices. A further set of papers examine the factors determining the decision to study overseas, for example Altbach (1991), Mazzarol (1998), Mazzarol and Soutar (2002), Nattavud (2005), encompassing studies of both personal and family characteristics, and university attributes that influence student university choice decisions. On the other hand, Pyvis and Chapman (2007) focus on the decision to attend an offshore campus in the home country.

Bourke (2000) offers one of the few analyses of the factors determining the choice of country in which to study, as well as the determinants of institution preference in which to study a particular subject, medicine. Our analysis differs from that of Bourke (2000) as we focus on Business Studies and Engineering students. These are the subjects in which there are the largest number of overseas students, as well as the largest number of universities offering these courses. In addition, we only focus on factors influencing students' choice of university, once a decision has already been made to study in the UK. There are also a number of methodological differences in our study, in particular our use of statistical data instead of survey data. Ford *et al.* (1999) look at the determinants affecting university choice for business students, but again they use survey data and for home rather than overseas students, in the US and New Zealand.

An advantage of our dataset is that we can investigate the impact of price on the demand of overseas students for UK undergraduate degrees at competing institutions. As such, the analysis contributes to the Student Demand Studies literature. Blaug (1981), as discussed in Woodhall (1991), offered an early UK contribution, estimating the impact on overseas student university demand from the introduction of full cost fees in the UK. Leslie and Brinkman (1987) discuss early contributions to the literature using US data, while Heller (1997) updated Leslie and Brinkman's US work and Cameron and Heckman (1999) provided a more recent US analysis. The consensus appears to be that fee increases have a negative impact on student demand.

The structure of the rest of this paper is as follows. In the next section we discuss our data and methods. Section III presents the results, while Section IV presents some concluding comments.

## II. DATA AND METHODS

The objective of this paper is to uncover the determinants of applications by overseas students to UK universities for undergraduate studies. This may be estimated as a demand function for places in higher education, and therefore depends on the price and quality of the product being purchased, as well as other factors. We focus on applications as opposed to the number of students since the number of students is subject to supply-side capacity constraints, whereas the number of applicants is not. Nevertheless, see Abbott and Leslie (2004) for an analysis of both applications and acceptances in UK universities. Our main estimated equation is:

$$\log(y_{it}) = \alpha_i + \gamma_t + \beta_1 P_{it} + \beta_2 Q_{it} + \beta_3 X_{1it} + \beta_4 X_{2i} + \varepsilon_{it} \quad (1)$$

Where  $y_{it}$  is the number of applications by overseas students,  $\alpha_i$  is the university-level effect,  $\gamma_t$  is the time effect,  $P_{it}$  is the fee charged to overseas students,  $Q_{it}$  is the quality of education provided,  $X_{1it}$  is a vector of time-varying variables,  $X_{2i}$  is a vector of time-invariant variables, and  $\varepsilon_{it}$  is a random error term.

### Data

Our sample covers 97 UK universities from 2002 to 2007 (see Appendix 1 for a list of the universities included). The sample includes all UK universities at the start of the sample period; although new universities have been established since then, we retain the same universities in the sample throughout to ensure consistency of the data. Table 1 provides the descriptive statistics for our main variables of interest. Data for the number of undergraduate applications is from UCAS, and is available for 19 subject areas using the JACS (Joint Academic Coding System), divided into the domicile of the applicants (Home, EU, Overseas) and the gender of the applicants. In this paper we use the number of applicants for the subject areas of Business Studies and Engineering. There are several reasons for the choice of these

two subjects. First, these are the two subjects with the largest populations of overseas students. Second, they are the subjects in which almost all of the universities in our sample are represented. Third, by having one laboratory-based subject and one classroom-based one, we are able to analyse any differences that exist between the behaviour of these two groups of applicants, for undergraduate degrees that often face different overseas student fee levels. Fourth, by restricting attention to individual subjects, we can to some extent overcome the problem that different universities may specialise in different subject areas, so that an analysis at the aggregate university level would capture not only differences in popularity across students, but also compositional differences in subjects across universities.

There are many applications by overseas students in both subjects. As shown in Table 1, there are slightly more applications by overseas male students in Business Studies as compared to female students, while there are many more male applicants in Engineering than female applicants. These patterns are also broadly reflective of the applications in these areas by Home students.

Our price variable is the fee charged by universities to overseas students. In most but not all universities, there are two fee bands at the undergraduate level for overseas students; a lower band for classroom-based subjects (including Business Studies), and a higher band for laboratory-based subjects (including Engineering). The data source is Reddin (2007). As shown in Table 1, the average fee for laboratory-based subjects is approximately £1400 more than the average fee for classroom-based subjects, with substantial variation both across universities and over time.

We use as our main measure of the quality of education provided, the rank of a university according to the relevant Times University Guide. A university's ranking is a composite measure based on teaching, student satisfaction, research, entry requirements, graduate employment, the proportion of good degrees awarded (i.e. 2.1 or first class), student/staff ratio, and the dropout rate. We also use subject rankings published by the Times University Guide, which are a composite measure based on teaching, research, entry requirements, and graduate employment. Engineering is in turn divided into six specialisms (Aeronautical and Manufacturing, Chemical, Civil, Electrical and Electronic, General, and Mechanical Engineering). Since we only have data for overall engineering applications, we take the

average score of a university across all engineering specialisms in which it is represented, and construct a new ranking based on this average score.

We recognise the potential problems of measures of quality as reported in published university guides, for example the measures published have been argued (HEFCE (2008)) to rely on information that is readily available rather than accurate measures of quality. Hence, these measures of quality may not be as closely correlated with National Student Survey (NSS) results as may have been expected. Nevertheless, official measures such as the NSS and the RAE capture only part of the overall quality of a university (teaching and research, respectively). Crucially, these measures are also much less readily available to potential students than measures found in university guides. In many cases such guides may be the only resource available to overseas students to make comparisons between universities.

In addition to price and quality, we control for other factors that may be important determinants of the attractiveness of individual UK universities to overseas applicants. Our control variables are the following. We control for distance from London to capture the importance of London as the economic, social and political capital of the UK (as well as its main transport hub), the number of applications in the same subject areas by home students to capture the overall popularity of the university in that subject, the fraction of the university enrolment comprising overseas students to capture the overall popularity of the university amongst overseas students, and a set of year dummies to control for year-specific fluctuations in the number of overseas applications caused by exchange rate fluctuations and other factors.

We experiment with other possible control variables, such as the presence of an English Premier League football team in the town or city of a university to test whether this increases the attractiveness of a university to overseas students. Dummy variables were created to indicate a plate glass university (universities built in the 1960s following the Robbins report on higher education), or a member of The Russell Group of universities, which identifies itself as “... an Association of leading UK research-intensive Universities...”, (see <http://www.russellgroup.ac.uk/>). See Appendix 1 for members of each (intersecting) group of universities. Some explanatory variables consistently turned out to be statistically insignificant, perhaps because of multicollinearity. These variables included the age of the university, dummy variables for whether the university has a medical school, whether the

university is a new (post-1992) university<sup>2</sup>, and climate variables such as temperature and average annual rainfall. Note in particular that universities vary widely in terms of their popularity with overseas students. For example, Glasgow Caledonian, Queen's Belfast, Central Lancashire and Ulster all have less than 2 percent of their students from overseas throughout our sample period, whilst at the other end of the spectrum, Imperial College and the London School of Economics have over 20 percent of their undergraduate students from overseas.

We also collected data on the number of overseas British Council education exhibitions attended by the university. However, data on this is available only for 2006 and 2007 so we were restricted to much smaller sample sizes. Nevertheless, this was the best proxy available for university international marketing activities, as data is typically not made publically available, even if collated by universities themselves.

## **Methods**

Equation (1) may be estimated using OLS, pooling observations across universities and over time. However, OLS does not take into account the panel nature of the data and can yield invalid inferences (see Baltagi (2005)). Instead of OLS, we therefore use the Hausman and Taylor (1981) estimator which takes into account the panel structure of the data. Our model selection process follows Baltagi, Bresson and Pirotte (2003) in using the Hausman (1978) test to select between alternative panel data estimators. First, we perform a Hausman test comparing the fixed and random effects estimators. If the null hypothesis of no systematic differences is not rejected, the random effects estimator is preferred since it yields the most efficient estimator under the assumption of no correlation between the explanatory variables and the errors.

However, if the Hausman test between fixed and random effects is rejected, then a second Hausman test is performed comparing the Hausman and Taylor (1981) estimator and the fixed effects estimator. The Hausman and Taylor estimator allows for some but not all explanatory variables to be correlated with the unobserved individual effects, unlike the fixed effects model which assumes that all the explanatory variables are correlated with the

---

<sup>2</sup> The Further and Higher Education Act 1992 allowed polytechnics to become universities. This Act has to date led to the establishment of 60 new universities.

individual effects (while the random effects estimator assumes that none of the explanatory variables are correlated with the individual effects). Failure to reject this second Hausman test implies the use of the more-efficient Hausman and Taylor estimator, whilst rejection implies the use of the fixed effects estimator. We report the results of these Hausman tests in the results section. The Hausman and Taylor estimator has the additional advantage over the fixed effects estimator in that it allows us to recover the parameter estimates of any time-invariant explanatory variables (such as distance from London, or membership of the Russell Group) which would otherwise be removed in the fixed effects transformation.

Initial research considered the possibility that price is endogenously determined, rather than an exogenous explanatory variable that may impact on applications. For instance, it may be that universities set their fees in response to demand conditions, so that there is a two-way relationship between applications and fees. Therefore, a 2SLS (Two Stage Least Squares) model was developed in which university overseas fees were instrumented using the other overseas fee level of a university (i.e. laboratory fees are instrumented using class-based fees, and vice versa) and a post-1992 university dummy. An efficient, 2-step GMM (Generalised Method of Moments) model was employed, with standard errors clustered by university to control for within-university correlation and heteroskedasticity in the error term. The Hansen (1982) J-test of overidentification suggests that the chosen instruments are appropriate. However, a Hausman test comparing OLS and 2SLS results indicated no systematic differences between the estimates. Results from the C-test of exogeneity (see Baum, Schaffer and Stillman (2003)) indicated that fees could be treated as exogenous and hence 2SLS methods were not required. The results of the 2SLS estimates are reported in Appendix 2.

### **III. RESULTS**

Tables 2 and 3 report simple correlations between the variables used in the econometric analysis. Table 2 shows that, whilst there is high correlation between the number of male and female overseas applicants in both Business and Engineering, the correlation across domiciles (e.g. between male overseas and male home applicants), and across subject areas (e.g. between overseas Business and overseas Engineering applicants) is much lower. Hence, although there is positive correlation in the number of applicants of different gender, subject and domicile, capturing the overall popularity of each institution in each subject, there is also

sufficient variation in the pattern of applications to suggest that institutional-level effects are not the whole story.

Table 3 reports the correlation between the log of the total overseas applicants (our dependent variable) and the principal independent variables used in the analysis. The correlations are strong and suggestive; fees are positively correlated with the number of applications. This appears to be contrary to standard demand theory, although of course the correlation table does not control for the effects of other variables. University rankings are negatively correlated with the number of applications; since university rankings are decreasing in quality with the best university ranked 1, this negative correlation indicates that better-ranked universities get more applications. Table 3 also shows that the number of overseas applications is positively correlated with existing stocks of overseas students and the number of British Council exhibitions attended by the university, and negatively correlated with the distance of a university from London. In our econometric analysis we will seek to explore whether all these variables have the same effects on the number of overseas applications, controlling for the effects of the other variables. Note also from Table 3 that many of the independent variables are highly correlated with each other; multicollinearity is a problem with this dataset, hence our parsimonious model specification.

### **Basic regression results**

Table 4 reports the results of regression equation (1). The results are obtained using the Hausman-Taylor estimator discussed above, with standard errors clustered by university to control for heteroskedasticity and within-university correlation in the error term. All regressions include year dummies to control for time-specific shocks such as exchange rate fluctuations which should impact all universities equally. All time-varying variables and all university-specific variables are assumed to be potentially correlated with the unobserved university effects. Column (1) reports the results for all applicants (Business and Engineering), column (2) for all Business applicants, columns (3) and (4) for male and female Business applicants respectively, column (5) for all Engineering applicants, and columns (6) and (7) for male and female Engineering applicants respectively. The Hausman diagnostic test results reported at the bottom of the table confirm the appropriateness of the Hausman-Taylor model: in every case, the first Hausman test rejects at 5% significance or better the

random effects estimator in favour of the fixed effects estimator, while the second Hausman test never rejects the Hausman-Taylor estimator in favour of the fixed effects estimator.

The fee charged by universities is never a statistically significant determinant of the number of applications for any group of students. This is an interesting result, as all the regressions control for the quality of the university, so that higher prices are not proxying for higher quality. There are at several possible explanations for this result. First, as can be seen in Table 3, fees are closely related to quality measures and hence the insignificance of fees may reflect the multicollinearity between these variables. Second, there may be other factors that influence both university fees and the number of applications that we are not capturing in our regressions. Third, it may simply be that, having decided to incur the expense of going to the UK for higher education, the difference in fees across universities plays little role in students' decision-making process.

An alternative explanation for the non-significance of fees may be obtained from signalling theory. Signalling theories such as that of Milgrom and Roberts (1986) and more recently Fluet and Garella (2002) suggest that a positive relationship between price and quality may be expected. Similarly, empirical evidence has confirmed that for a broad range of products price and quality are positively correlated, although as in the current analysis, the correlation is not perfect, for example Caves and Greene (1996). It may be that the positive effects of signalling completely offsets the negative effects that would be expected from consumer choice theory.

Considering the other principal explanatory variables included in the model, Business Studies students appear to be influenced by the overall ranking of the university, a feature shared with female but not male Engineering students. This may indicate that different groups of students value different characteristics of universities when making their applications. Both Engineering and Business Studies students typically apply to universities that also attract higher numbers of Home applications in the same subject areas, and that have greater existing overseas student populations. The positive relationship between applications and existing overseas student populations may reflect the possibility of direct word of mouth recommendations, or the perception that these universities are better-equipped to deal with the needs of overseas students. The positive relationship between overseas and Home applications may reflect the overall popularity of the university or some reputational

advantage which is not captured by the university rankings. All overseas students are also attracted to universities with greater proximity to London, thus confirming the hypothesis that students are attracted to the city.

Finally, the time dummies indicate that, controlling for the other factors, the number of applications increased in both subject areas over time, but there is evidence of a decrease in the number of applications in 2006 and 2007 (the excluded year is 2002). Since these two subjects are where the majority of overseas students are concentrated, this decrease may have important implications for the UK university sector.

### **Robustness**

The regressions were repeated adding additional explanatory variables to test whether they also had a significant impact on overseas applications, but in so doing, the results offer a robustness check on the results reported in Table 4. The results of these regressions are reported in Table 6, while Table 5 reports the simple correlation between the different measures of quality; these correlations are very high, suggesting a cautious interpretation of the results of Table 6. Nevertheless, the robustness of the previous results is confirmed, with the coefficients on each of the fees variables always again insignificantly different from zero, while overseas applicants remain attracted to universities already popular with both home and overseas students. Most students remain attracted to universities closer to London, although applicants do not seem to be similarly attracted to other UK major cities; the population of the city in which the university is located, is not significantly related to the number of applications. The Hausman tests again support the use of the Hausman-Taylor estimator in preference to both fixed and random effects models.

The results in Table 6 include dummy variables controlling for plate glass and Russell Group universities (see the discussion in the data section above), as well as dummies for universities in Scotland, Wales and Northern Ireland. Membership of the Russell Group has a positive and often significant impact on student applications, even after controlling for other measures of quality. Universities located in Scotland or Wales do not have any additional advantage or disadvantage relative to those located in England beyond the impact of distance from London. Scottish universities' four-year degree structure (as opposed to three years in England, Wales and Northern Ireland) does not appear to reduce the demand for their

degrees. Business Studies applicants (but not Engineering applicants) appear to have a preference for plate glass universities, but not for Northern Irish universities, although the reason for these results is not clear. This highlights the different factors affecting different groups of students' decisions. Similarly, the result that the presence of an English premier league football team has a positive, significant impact, at the 5% significance level, on university applications from female Engineering students but no other student group, again reflects possibly unexplainable differences between the groups of students in our sample.

In Table 6 the overall Times Guide university rankings are supplemented with subject specific Times Guide rankings<sup>3</sup>. Once again we find that Business Studies students are influenced by rankings, both overall university rankings and the relevant subject specific rankings, but that rankings do not generally seem to impact on Engineering students' university decisions, with just female Engineering students found to be influenced by overall university rankings at a 5% significant level. We can only speculate as to the reason for this result, but noting the magnitudes of the correlations reported in Table 5 between The Times Guide rankings and university groupings, presume that if Engineering students do consult quality rankings then the result reflects multicollinearity between explanatory variables.

Finally, in Table 7, we re-run the regressions in Table 4, but include the number of British Council exhibitions attended by each university, as a proxy for the international marketing activities of the universities. Unfortunately, data was only available for the last two years of our dataset, considerably reducing the number of observations available. The results for the other variables of interest are broadly similar to that in previous tables. Nevertheless, the striking result emerges that the number of British Council exhibitions attended is never found to have a significant impact on overseas applications. We speculate that this can be at least partly explained by students increasingly having recourse to a greater number of alternative sources of information, including university web pages and university guides. Attendance at exhibitions may then be in the hope of obtaining a favourable impression of a university, reinforcing information messages already received by an applicant.

---

<sup>3</sup> We also have data on the individual components of the rankings. Whilst it may be of interest to explore which of these individual components have the greatest impact on application numbers, these components are very highly correlated with one another (see Appendices 3a to 3c), so that a multiple regression controlling for all components simultaneously may not be informative, while including each component separately would mean that we are not appropriately controlling for other potential determinants and so would not be able to determine the relative importance of different components.

## IV. CONCLUSIONS

This paper investigates empirically the factors influencing overseas students' decisions to apply to UK universities to study Business Studies and Engineering, using an original dataset of 97 UK universities from 2002 to 2007. The analysis considers the impact on applications of fees, university characteristics and quality indicators reported in university guides. The analysis indicates which information and factors students use when selecting UK universities to apply to. Overseas students are found to be influenced by quality indicators such as quality rankings, although interestingly Engineering and Business Studies students are influenced by different quality indicators, with Business Studies students typically significantly influenced by university and subject specific guide rankings. Nevertheless, all overseas students in the sample prefer to be close to London and other overseas students, and are found to have similar preferences to home students, when selecting universities to apply to. Of particular note are two results: first, fees do not have a significant impact on application decisions and potential explanations for this result are explored; and second, a university's attendance at British Council exhibitions does not have a significant affect on student applications to study either Business Studies or Engineering.

These results are expected to be particularly relevant to university policymakers. While universities cannot move nearer to London, they can consider the nature of the marketing activities undertaken, with an awareness that some forms of marketing may be ineffective. One promising alternative to participation in British Council exhibitions may be to form partnerships with foreign institutions of higher education, which, if successful, may attract greater numbers of overseas students, which may have positive effects on future overseas applications.

Education is an example of an experience good, for which much information can be collected in advance, but perfect information can never be obtained. It is therefore interesting to identify the weights attached by possible overseas applicants to general and subject specific quality rankings as are published in guides such as The Times University Guides. Our results suggest that universities have some flexibility to charge fees higher than rival institutions without adversely affecting application numbers, but the relatively small range of fees within the dataset implies that this result should be acted upon with caution.

## Appendix 1: Universities included in the sample.

Anglia Ruskin University	* University of Cambridge
Aston University	University of Central Lancashire
Bournemouth University	University of Derby
Brunel University	University of Dundee
* Cardiff University	University of Durham
City University	# University of East Anglia
Coventry University	University of East London
De Montfort University	* University of Edinburgh
Glasgow Caledonian University	# University of Essex
Goldsmiths College	University of Exeter
Heriot-Watt University, Edinburgh	University of Glamorgan
* Imperial College London	* University of Glasgow
Keele University	University of Gloucestershire
* Kings College London	University of Greenwich
Kingston University London	University of Hertfordshire
# Lancaster University	University of Huddersfield
Leeds Metropolitan University	University of Hull
Liverpool John Moores University	# University of Kent
London Metropolitan University	* University of Leeds
London South Bank University	University of Leicester
Loughborough University	University of Lincoln
* London School of Economics	* University of Liverpool
Manchester Metropolitan University	University of Nottingham
Middlesex University	* University of Oxford
Napier University	University of Paisley
Newcastle University	University of Plymouth
Northumbria University	University of Portsmouth
Nottingham Trent University	University of Reading
Oxford Brookes University	University of Salford
Queen Mary, University of London	* University of Sheffield
* Queen's University Belfast	* University of Southampton
Roehampton University	University of St Andrews
Royal Holloway	University of Stirling
Sheffield Hallam University	University of Strathclyde
School of Oriental & African Studies	University of Sunderland
Staffordshire University	University of Surrey
Thames Valley University	# University of Sussex
The Robert Gordon University	University of Teesside
* The University of Manchester	University of Ulster
UCE Birmingham	University of Wales Aberystwyth
* University College London	University of Wales Bangor
University of Aberdeen	University of Wales Lampeter
University of Abertay, Dundee	University of Wales Swansea
University of Bath	* # University of Warwick
* University of Birmingham	University of West of England
University of Bradford	University of Westminster
University of Brighton	University of Wolverhampton
* University of Bristol	# University of York
University of Buckingham	

Notes: \* indicates a member of The Russell Group of universities. # indicates a plate glass university.

Observations	554	528	528	526	496	495	478
Hausman test chi2	0.00	-0.69	-0.43	-0.32	0.02	0.02	0.50
p-value	1.00	1.00	1.00	1.00	1.00	1.00	1.00
Underidentification $\chi^2$	29.46	42.03	42.03	41.57	52.38	52.39	55.44
Weak identification F	53.59	26.29	26.29	25.69	243.11	241.49	248.38
Hansen J-test p-value	0.58	0.83	0.84	0.81	0.47	0.44	0.17
Endog. of fees p-value	0.74	0.50	0.51	0.59	0.88	0.89	0.37

Notes: Absolute value of z statistics in parentheses. + significant at 10%; \* significant at 5%; \*\* significant at 1%. Estimation method is 2SLS using efficient 2-step GMM, with standard errors clustered by university. University fees for Engineering students is instrumented using fees for Business Studies students and a post-1992 university dummy, while university fees for Business Studies students is instrumented using fees for Engineering students and a post-1992 university dummy. The Hausman test is the test for equality of parameter estimates between OLS and 2SLS. Underidentification chi2 is the chi-squared of the LM test for whether or not the equation is identified. Weak identification F is the F-statistic of the Wald test for weak correlation between the instruments and the instrumented variable. The Hansen J-test is the test for over-identification. The test of whether or not fees are endogenous is the C-test (see Baum, Schaffer and Stillman (2003) for details).

### Appendix 3a: Correlation between the components of the Sunday Times Ranking

	Times Rank	Teaching	Research	Entry score	Student-staff ratio	Library & computer spend	Facilities spend	Good degree	Employment	Completion rates
Times Rank	1.0000									
Teaching	-0.2855	1.0000								
Research	-0.8700	0.2049	1.0000							
Entry score	-0.1688	-0.4435	0.2433	1.0000						
Student-staff ratio	0.7126	-0.2549	-0.6348	-0.0476	1.0000					
Library & computer spend	-0.6170	0.0557	0.5781	0.2773	-0.5489	1.0000				
Facilities spend	-0.5406	-0.0561	0.5202	0.3148	-0.3615	0.3939	1.0000			
Good degree	-0.8515	0.1910	0.7886	0.2332	-0.6439	0.6229	0.4327	1.0000		
Employment	-0.2729	0.2806	0.0512	-0.5462	-0.2240	-0.0085	-0.1195	0.1483	1.0000	
Completion rates	-0.8204	0.1905	0.7142	0.1613	-0.4932	0.4820	0.3801	0.7002	0.2831	1.0000

Note: Sample size is 538 for all correlations reported.

### Appendix 3b: Correlation between the components of Business Ranking

	Business Rank	A-level score	RAE score	Destination score	Teaching quality
Business rank	1.0000				
A-level score	-0.8234	1.0000			
RAE score	-0.8608	0.6979	1.0000		
Destination score	-0.6089	0.1650	0.4390	1.0000	
Teaching quality	-0.3048	0.3103	0.2398	0.1873	1.0000

Note: Sample size is 142 for all correlations reported.

### Appendix 3c: Correlation between the components of Engineering Ranking

	Engineering Rank	A-level score	RAE score	Destination score	Teaching quality
Engineering rank	1.0000				
A-level score	-0.8438	1.0000			
RAE score	-0.7800	0.7421	1.0000		
Destination score	-0.7180	0.5698	0.4847	1.0000	
Teaching quality	-0.7166	0.5699	0.5455	0.4318	1.0000

Note: Sample size is 217 for all correlations reported.
